Fermi Level Pinning at the PolySi/Metal Oxide Interface

APRDL, Digital DNA Laboratories, Motorola, Austin, TX

We report here for the first time that Fermi pinning at the polySi/metal oxide interface causes high threshold voltages in MOSFET devices. Results indicate that pinning occurs due to the interfacial Si-Hf and Si-O-Al bonds for HfO₂ and Al₂O₃, respectively. This fundamental characteristic also affects the observed polySi depletion. Device data and atomistic simulation results will be presented.
